

a

Energy = mean annual temperature; Water = annual precipitation; Productivity = NPP; Heterogeneity = within-cell elevation range; Seasonality = temperature seasonality; Human = human footprint.
 Dots: BH-adjusted $P < 0.05$. Every model controls for all six predictors at once, so each cell is that hypothesis's unique effect.

**b**

Climate dominates in every class; human pressure is largest for reptiles

**c**

Pace = size + fecundity; Niche = habitat breadth + range size. Spread is across the six hypotheses
